

## **Final project report**

---

<i>Project ID</i>	2004/8.01
<i>Title</i>	CANOPO, the role of the Atlantic sector of the Southern Ocean in CO2 sequestration
<i>Principal investigator</i>	Vincenzo Artale
<i>Institution</i>	ENEA
<i>Email</i>	<a href="mailto:vincenzo.artale@enea.it">vincenzo.artale@enea.it</a>
<i>Duration</i>	3 years
<i>Assigned funding</i>	120.000,00 Euro

---

### **Activities and results**

During the project three oceanographic cruises were performed on board of the Argentinean ice breaker "Almirante Irizar" in the three austral winters 2004-2005, 2005-2006 e 2006-2007. XBT and XCTD data were collected on the Drake Strait, the Weddell Sea and between the northern tip od the Antarctica Paeninsula and the Orcadas Islands. Totally during the three crusies were collected 451 temperature profiles with XBT and 35 profiles of temperature and salinity with XCTD pobes. All the logistic was in charge of the Argentinean Navy, the "Instituto Antartico Argentino" (IAA) and the Direccion Nacional del Antartico Direccion National Antartica (DNA).

The main aim of the project was the study of the variability of the Mixed Layer and the estimate of the heat content on the first 700 m of the water column, and the large scale representation of the surace and subsurface structure of the ACC.

Data from the Weddell sea were used to estimate the changes in temperature of the Warm Deep Water (WDW). Data fom the Drake Passage were used to estimate the baroclinic transport, using WOCE section on the same area to infer statistical relaton between temperatures and salinities.

3D OGCM models were used to study by means of Lagrangian diagnostics the water mass transformations on the Southern Ocean and therir interannual variability. In particular the representation of the downwelling-upwelling cycle was reconctructed positioning particles on the water formation area and integrating them til the momemt they resurface.

The bio geochemical model PISCES was used to study the relative role of the biological and physical pump in the Southern Ocean with the aim of under standing the main mechanism of the CO2 sequestration.

During the project was elaborated an experimental methodology useful to estimate the ML depth by means vertical profiles of temperature and salinity, using also data from CANOPO cruises.

Finally, was investigated the role of the coherent structures, peculiar of the 2D geostrophic turbulence, on the ACC dynamics analyzing historical Lagrangian Data.
