

Final project report

<i>Project ID</i>	2004/8.03
<i>Title</i>	CLIMA IV - Ventilation processes in the Ross Sea
<i>Principal investigator</i>	Prof. Giancarlo Spezie
<i>Institution</i>	Università degli Studi di Napoli "Parthenope"
<i>Email</i>	giancarlo.spezie@uniparthenope.it
<i>Duration</i>	3 years
<i>Assigned funding</i>	280.000,00 Euro

Activities and results

We carried out three oceanographic surveys in the Ross Sea and adjacent areas during the period 2004-2010 focused on the formation of deep and bottom waters. To realize such topics we focused our attention on the atmospheric- oceanic processes in the polynya areas, on the thermohaline changes over the shelf, on the ventilation processes at the shelf break between the outflow of (new) shelf waters and the inflow of (old) deep waters of oceanic regime carried by the Antarctic Circumpolar Current.

During the austral summer 2005-06 we performed a basin scale multidisciplinary (bio-geo-chemical and physical) oceanographic survey to recover the existing moorings in the Ross Sea and to redeploy all of them for a further season as well as to extend the hydrographic surveys obtained during previous cruises in strategic areas of the Ross Sea in order to study the origin and the fate of the shelf water and their role in the AABW formation. Moreover we collect XBT, CTD/LADCP data and water samples also during transfer between New Zealand to the Ross Sea; underway continuous surface (-5 m) salinity and temperature measurements were made along all the cruise track.

During the austral summers 2007-2008 and 2009-2010 only the mooring activity (recover/redeploy) in the Ross Sea was performed.

Main results obtained concern:

- Identification of the source areas and major pathways of the shelf waters observed south of the slope front; this includes waters formed by exchange with the atmosphere as well as by interaction with ice shelves.
- The identification and quantification of biomarkers associated with the waters of shelf and are tied to specific biological activity.
- The quantification of the flow of particulate matter in relation to the physical structure.
- The definition of the concentration, the characteristics and processes of the benthic layer influenced by water dynamics.
- The estimate of the penetration of anthropogenic CO₂ and the role of the Ross Sea in the global budget.
- The quantification exporter of vertical particulate matter (biogenic and lithogenic components).
- The definition of a carbon budget inclusive of passive transport processes, active transfer and recirculation through the planktonic food webs.
- The role of labile Fe and Cu in modulating the primary production in Terra Nova Bay polynya
- Study the structure of the slope front and the exchanges across the front.
- Surface heat budget of the Ross Sea (ocean-ice-atmosphere).
- Estimations of the mean time between formation of these waters and exchange across the slope front.
- Analysis of the dynamics and interannual variability of the ACC and related thermal fronts, including the generation of eddies.
